Overview

This document contains the exploratory statistical analyses of the EMG4 data combined with the embedded ratings, justice and fairness scores.

Load preprocessed MLM EMG data

1. Embedded Ratings

For exploratory reasons, we also look at the correlation between the EMG signal at the character morality segment and the ratings on the embedded rating task. We focus on the peak of the differential effect, which occurs 3-4s after the onset of the segment. The higher the rating score, the more moral the behavior was judged. So we expect to find a negative correlation, more frowning to immoral behavior (i.e. lower scores).

Check the normal distribution of the morality responses

Q-Q plot to check normality om EMG results at the Morality segment.

The averaged EMG data are not normally distributed, so we take the log transform.

Plot the relation between centered embedded rating and log corrugator EMG at the peak at the Morality Segment

Scatterplot between the centered embedded rating and log corrugator EMG at the peak at the Morality Segment.

Pearson's product-moment correlation: embedded ratings and morality EMG signal

```
##
## Pearson's product-moment correlation
```

```
##
## data: embed_rating and Morality_mean_log
## t = -14.175, df = 3699, p-value < 2.2e-16
## alternative hypothesis: true correlation is not equal to 0
## 95 percent confidence interval:
## -0.2573231 -0.1962015
## sample estimates:
## cor
## -0.2269858
```

There is a weak negative correlation: $r(3699) = -0.2269858$, $p = 1.8672345 \times 10^{-44}$.

As expected, the lower the rating, the higher the corrugator EMG activation. There were some NA ratings and some trials were excluded in the baseline procedure. In total there was a data loss of 3.6197917%.

2. Justice score

2.0 Load final MLM models from the regular analysis

2.1 Justice score and EMG signal at morality segment

The best model was Morality12: $\text{Morality_response} \sim \text{MoralityCondition} + \text{t1_immoral} + \text{t1_moral} + \text{t2_immoral} + \text{t3_immoral} + (1 + \text{MoralityCondition} \mid \text{sjCode}) + (1 \mid \text{Markertrial})$. We now add our justice score to that model and check whether it improves the fit.

```
load(paste0(getwd(), "/WORCS_EMG4/results/EMG4_MoralityJustice_final_model_60sjs.RData"))
load(paste0(getwd(), "/WORCS_EMG4/results/EMG4_Morality_js_model_60sjs.RData"))

anova(MoralityM12_js, MoralityM12_justice_score) # p = .068, so MoralityM12_js is the better model

## Data: justice_mor_data
## Models:
## MoralityM12_js: Morality_response ~ MoralityCondition + t1_immoral + t1_moral + t2_immoral +
t3_immoral + (1 + MoralityCondition | sjCode) + (1 | Markertrial)
## MoralityM12_justice_score: Morality_response ~ MoralityCondition * justice_score + t1_immoral +
t1_moral + t2_immoral + t3_immoral + (1 + MoralityCondition | sjCode) + (1 | Markertrial)
## npar AIC BIC logLik deviance Chisq Df

## ---
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Adding the justice score to the MoralityM12 model does not improve the fit of the model ($p = .068$).

2.2 Justice score and EMG signal at state adjective segment

The best model is Adjective17: $\text{StateAdjective_response} \sim \text{MoralityCondition} + \text{StateAdjectiveCondition} + \text{MoralityCondition}:\text{StateAdjectiveCondition} + \text{t1_moral_neg} + \text{t1_moral_pos} + \text{t2_immoral_neg} + \text{t2_moral_neg} + (1 + \text{t1_moral_neg} + \text{t2_immoral_neg} \mid \text{sjCode}) + (1 \mid \text{Markertrial})$.

2.2.1 Probing the 3-way interaction

We can probe the 3-way interaction, provided we choose specific values for the justice scores. The scores range from -0.2941176 to 1.4705882, since -1.2353 was an outlier we choose the values from -0.5 till 1.5 with increments of 0.5.

Table 3 Estimated Marginal Means for the State Adjective Segment at different levels of the Justice score.

2.2.2 Plotting the 3-way interaction

Plot of regression lines for the different categories of Morality and Valence.

Figure on State Adjective segment for different justice scores

People with high vs, low justice trait scores have different responses in the moral conditions compared to the immoral conditions, as was indicated by the significant 3-way interaction (see Table 2, $b = -20.93$, $z = -4.97$, $p < 0.001$).

In the moral condition the participants who scored low on the justice trait score (i.e. people who do not agree to want positive things for good people and negative things for bad people) do not show a differential response towards the positive and negative state adjectives. Participants who were indifferent, or agreed to want positive things for good people and negative things for bad people, i.e. have a higher justice score, frowned more in response to negative state adjectives compared to positive state adjectives. As per our multiple-drivers model frowning at negative state adjectives for moral characters could be the net result of negative simulation and additional negative evaluation (unfair). Our justice trait score seems to influence the degree of frowning in this case, hinting at a possible attenuation of the negative evaluation. Only participants who value a 'sense of justice' frown at unfair events that befall a moral character.

Interestingly, in the immoral conditions all participants, irrespective of their justice score, frowned more in response to negative state adjectives than to positive state adjectives. This pattern can be explained by negative simulation rather than evaluation, as the evaluation would counteract the simulation force yielding no differential responses or even a flipped response pattern. This is clearly not the case. However, the higher the justice score, the higher the overall response was (see Table 2, $b = 10.66$, $z = 4.02$, $p < 0.001$).

2.3 Justice score and EMG signal at affect reason segment

The best model is Reason22: AffectReason_response ~ MoralityCondition + StateAdjectiveCondition + MoralityCondition:StateAdjectiveCondition + t1_moral_neg + t1_moral_pos + + t2_moral_neg + t3_moral_neg + (1 + t1_moral_neg + t3_moral_neg | sjCode) + (1 | Markertrial).

```

2.3.2 Plotting the 3-way interaction

Plot of regression lines for the different categories of Morality and Valence.

Figure on Affect Reason segment for different justice scores

People with high vs, low justice trait scores have different responses in the moral conditions than in the immoral conditions, as was indicated by the significant 3-way interaction (see Table 7, $b = -42.13$, $z = -12.39$, $p < 0.001$).

In the moral condition, similar to the responses at the state adjective, participants frowned more in response to negative state adjectives compared to positive state adjectives and this difference increases as their justice score increases. As per our multiple-drivers model frowning at negative state adjectives for moral characters could be the net result of negative simulation and additional negative evaluation (unfair). Our justice trait score seems to influence the degree of frowning in this case, hinting at a possible attenuation of the negative evaluation. Participants who stronger value a 'sense of justice' frown substantially more at unfair events that befall a moral character.

Interestingly, in the immoral conditions participants, with a low to moderate justice score, frowned more in response to negative state adjectives than to positive state adjectives. This pattern can be explained by negative simulation rather than evaluation, as the evaluation would counteract the simulation force yielding no differential responses or even a flipped response pattern. This is clearly not the case. However, for participants with a higher justice score the pattern starts to flip. For the participants with the highest justice score we see that they frown more in response to positive state adjectives than negative state adjectives (see Table 9, $b = -8.41$, $t = -3.56$, $p < 0.001$). This is the pattern that we had hoped to find overall and would indicate a counteracting force of fair evaluation and negative simulation of negative events befalling an immoral character.

3. Fairness ratings

With the Story Fairness rating responses we were able to explore if and how the hypothesized effect of fairness-based evaluation would be reflected in a self-report measure as evaluation for this response

tends to occur on a more conscious level. Therefore, we built a linear mixed model again focused on the interaction between the fixed factors morality condition (moral, immoral) and event valence (positive, negative) and with subject and item as random effects, but now with the Story Fairness ratings as the outcome measure. We also performed pairwise comparisons to investigate significant effects.

A combined amount of 87 ratings from 7 different participants were excluded from the analysis due to an error in the creation of the four versions of the Story Fairness Tasks (corresponding to the four versions of stimuli lists). These issues were quickly fixed so the data of all other participants was complete. Furthermore, there was 1 participant whose ratings on all 64 narratives were excluded from analysis as everything was rated as neutral. This resulted in a total data loss of 4.0625%.

A summary of the distribution and the means of the 4 conditions:

Figure on Fairness Ratings

3.2 Fairness rating and Justice Score

The model for Fairness was FairnessM1: $\text{fairness_rating} \sim \text{MoralityCondition} * \text{StateAdjectiveCondition} + (1|\text{sjCode}) + (1|\text{Markertrial})$. We now add our justice score to that model and check whether it improves the fit.

```
## Data: justice_fairness_data
## Models:
## FairnessM1_justice: fairness_rating ~ MoralityCondition * StateAdjectiveCondition + (1 | sjCode)
+ (1 | Markertrial)
## FairnessM1_justice_full: fairness_rating ~ MoralityCondition * StateAdjectiveCondition *
justice_score + (1 | sjCode) + (1 | Markertrial)
## npar AIC BIC logLik deviance Chisq Df Pr(>Chisq)
## FairnessM1_justice 7 11946 11990 -5966.2 11932

Positive Immoral - Negative Immoral	-0.89	3622.53	-1.20	-0.58	-7.60	<0.001

3.2.2 Plotting the 3-way interaction

Plot of regression lines for the different categories of Morality and Valence.

Figure on Fairness Ratings for different justice scores

People with high vs, low justice trait scores have different responses in the moral conditions than in the immoral conditions, as was indicated by the significant 3-way interaction (see Table 15, $b = 1.33$, $z = 7.97$, $p < 0.001$).

The patterns for moral and immoral conditions are similar with respect to the influence of justice score. Participants who stronger value a 'sense of justice' gave more extreme ratings, i.e. stronger fair judgments in fair situations and stronger unfair judgments in unfair situation. So the fairness judgments are positively related to the justice scores. What seems to happen is that the differential rating between positive and negative affect reasons is larger for participants with a higher justice score.
